WHO WE ARE

Galileo Galilei once said ‘measure what is measurable and make measurable what is not so.’ Four hundred years later, this is exactly what we do. We’re a family-owned company specialised in high quality mechanical process instrumentation. Founded back in 1957 as a production- and repair shop for thermometers, today we are a leading manufacturer of diaphragm seals, pressure gauges, temperature gauges, thermowells, valves and manifolds. We have offices and facilities in Europe, the Middle East, India, the Far East, and Americas.

A PASSION FOR EXCELLENCE

Our mission is to create the best process instruments on the market. But we believe the way we make those instruments is just as important. In everything we do, quality is leading. It’s something we never compromise on. Whether we’re talking about the raw materials we use, our production processes, the way we service our customers or simply the state of our end product: if it’s not great, it’s just not good enough.

GETTING THE JOB DONE

We operate in a field where solutions aren’t always easy. At times, they might even seem impossible. That’s where we excel. Not only do we conceive, develop and produce instruments that let you accurately monitor your processes, we also offer 24/7 assistance to keep your business running smoothly. From off-the-shelf products to custom-made innovations, we take pride in delivering the right answer to your needs – no matter how complex they are.

WORKING TOGETHER

Our passion for quality extends into our customer service. Our technical support team works with you every step of the way, making sure you optimally benefit from our products. Drawing on our vast knowledge of a wide range of industries, we’ll guide you through the instrument selection process and provide technical support throughout and after completion of the project. Backed up by our dedicated maintenance and repair service, you can always rely on our instruments to carry out the task they were designed for.

PERFORMANCE THROUGH INNOVATION

How can we make things better: it’s the one question that’s constantly on our minds. We’re always looking for ways to optimize our product efficiency, ease of installation, packaging and durability. Some of these changes are so small, you might not even notice them. But others may be significant, such as the addition of a new product to our range. Whatever their impact, our innovations are always born out of our ambition to create better products and services, so you can excel in delivering yours.

INTRODUCTION

Modern chemical processing and process manufacturing procedures demand ever greater accuracy and reliability from their pressure, level and flow measuring instruments. This is important to minimise costs, and to keep production downtime and shut downs to an absolute minimum. In various situations it is necessary to isolate and therewith protect the pressure measuring instrument from the process medium in order to maintain the required accuracy and reliability objectives. This isolation or separation of the instrument and the process is typically done by means of Diaphragm Seals, to protect the vulnerable measuring instrument. This protection enhances the lifetime of the measuring instrument significantly.

Before the start of any project related to the pressure, level and flow applications one should understand the possibilities of Diaphragm Seals. Badotherm's expertise and experience are there to ensure that the right solutions are offered to meet the needs from the start and prevent any problems at a later stage. When Diaphragm Seals are needed the material characteristics, operating conditions for the instruments, and choice of mounting should be taken into account.

OPERATING PRINCIPLE

A Diaphragm Seal System consists of a measuring instrument, typically a pressure transmitter or pressure gauge, with one or two Diaphragm Seals and either a direct mount construction or with capillary lines, filled with a fill fluid. A correctly prepared and filled Diaphragm Seal System will accurately transfer process pressure on the diaphragm to the sensing element of the measuring instrument. This is based on Pascal's principle which states that a pressure exerted on a fluid is transmitted undiminished through that fluid in every direction. The figures presents a schematic overview of this operating principle:

The process pressure exerts a force on the outside face of the seal, the flexible diaphragm. As the diaphragm flexes under this force it pushes inwards and attempts to compress the transmission or fill fluid behind the diaphragm. The transmission fluid is designed to withstand compression so the force is channelled proportionally and directly in to the measuring instrument to produce a resultant reading on the connected instrument.

WHEN TO USE DIAPHRAGM SEALS

Diaphragm Seals are typically used to protect the measuring instrument. There are many different situations in which a Diaphragm Seal should be typically considered:

- **Corrosive medium:** When the process medium is corrosive it would chemically attack the wetted parts of a standard pressure measuring instrument.
- **Viscous medium:** When the process medium is highly viscous or contains solid particles, either of which could result in the instrument's pressure inlet getting blocked.
- **Solidification:** When the process medium is prone to solidification, crystallization and/or polymerization over time. The medium may freeze when the temperature drops, it may set as it dries, or it may be subject to polymerisation. In these situations the pressure inlet can get blocked.

- **High/low temperatures:** When the process medium temperature is very high or very low and exceeds the temperature limits of the pressure measuring instrument resulting in damaged measurement instruments.
- **Sanitary requirements:** When the process is easily affected by the formation of bacteria on or in the process connection. The presence of bacteria in the process medium can lead to rejection of production batches. These applications where hygiene is of paramount importance are often found in the pharmaceutical, food and beverage industry.
- **Specific process connections:** When the location of the pressure measurement is not suitable for a direct mounting of a pressure measuring instrument. A diaphragm with remote mounting, by means of capillary, ensures easy visual check of the instrument.
- **Replacing 'wet legs':** As a substitution for so-called 'wet legs' for liquid level measurements in pressure retaining tanks.
- **Hydrogen permeation:** Also Diaphragm Seals are used when in the process there is a chance of presence of hydrogen ions (H+) that can permeate the diaphragm. In those cases, a diaphragm seal with gold plating offers the required protection.
- **Mounting effect:** The mounting effect on a Diaphragm Seal System is the variation in the pressure represented by the vertical fill fluid column between the Diaphragm Seal and the instrument, due to the variation of the gravity of the fill fluid as a result of ambient temperature deviation.
- **Zero shift:** The most common application of Diaphragm Seals is a level measurement. Proper ranging of a transmitter for level service requires considering the specific gravity of both the fill fluid and the process fluid, and the transmitter range.
- **Temperature effect:** Changes in volume of the Diaphragm Seal System are referred to as temperature effects. They are caused by changes in volume and density of the fluid in the system and occur when the fill fluid expands or contracts caused by fluctuations of the process and/or ambient temperatures. This change in fill volume drives a change in the internal pressure of the Diaphragm Seal System.
- **Diaphragm characteristics:** The characteristics of the diaphragm itself are important for the performance. In general, a larger diaphragm diameter allows for more flexibility and is more sensible to changes in the volume due to temperature influences. Other diaphragm characteristics as the material, the thickness of the diaphragm as well as the convolution pattern, are an important factor as they all have an effect on the performance of the Diaphragm Seal System.
- **Fill fluid characteristics:** Each fill fluid has its own characteristics, such as density, viscosity, thermal expansion, and vapour pressure. These characteristics are influenced by the systems pressure and temperature and determine the performance of the Diaphragm Seal System. The selection of the fill fluid depends on factors such as temperature, pressure, volume to be displaced (response time) and process safety. Most used fill fluids are silicone oil, glycerin, or vegetable oils. Also special inert fill fluids, such as Halocarbon® for chloride and oxygen applications and other special filling fluids for high temperatures (up to 410 °C) are used.

PERFORMANCE CONSIDERATIONS

Mounting a Diaphragm Seal to a pressure instrument changes the performance of the instrument. The Diaphragm Seal System will have additional temperature effects and response time depending on the system configuration. The performance of the entire Diaphragm Seal System needs to be evaluated when specifying a new application to ensure satisfactory performance when mounted in process.

- **System volume:** The fill volume in the Diaphragm Seal System needs to be minimized as much as possible. The more volume in the system, the higher the (potential) effect of temperature. For better performance always keep the system volume as small as possible, for instance by keeping capillaries as short as possible. Also it is advised not to use different capillary lengths at HP and LP of a DP measurement.

BASECAL

BaseCal is Badotherm's web-based Diaphragm Seal performance calculation software. BaseCal simplifies the proper selection of Diaphragm Seal transmitter combinations. Regardless the application (flow, pressure, level, etc), users can select the Diaphragm Seal System for the needs of the application. The software requests you to fill out the application parameters and will then calculate the correct calibration range. BaseCal considers the following application variables:

- Mounting style
- Differential, absolute or gauge application
- Ambient and process temperature
- Operating and design pressure
- Filling fluid volume, thermal expansion and vapour pressure characteristics
- Diaphragm seal type
- Diaphragm diameter and material
- Capillary length and inside diameter

In BaseCal the Badotherm Diaphragm Seal types can be selected together with the brand and type of transmitter required. BaseCal will calculate the total performance of the diaphragm seal/transmitter combination expressed as TPE (total probable error) and the response time of the system at several temperatures. An account can be obtained at www.Basecal.com.

INTRODUCTION

Diaphragm Seals on instruments are used to measure pressure. Pressure can be described as a force applied on a surface. There are different ways of expressing pressures. It can be expressed in kilogramforce per square centimetre (kgf/cm²), whereby kgf stands for a force and cm² for the surface the pressure is applied on. Same is valid for the commonly used Pounds per Square Inch (PSI). Pressure can also be expressed in various other units and most common are: bar, mbar, kPa and MPa, mmHG = Torr (vacuum measurement), mmH₂O, inchH₂O. The pressure that is present on a daily basis is the atmospheric pressure, which averages at 101,325 kPa.

In the industry pressure is typically used to create a chemical or physical reaction. By either raising or reducing the pressure a reaction takes place to obtain the desired result or product. This change to atmospheric pressure can be done by either heating or boiling a gas or fluid, by pumping a gas or fluid, by compressing a gas or by a chemical reaction as a result of mixing several substances. To control this process and to prevent that it runs out of control, these changes to atmospheric pressure need to be measured accurately.

ABSOLUTE-, GAUGE-, AND DIFFERENTIAL PRESSURE

Depending on what to measure, three sorts of pressures have been defined. They are differentiated by the zero reference used:

ABSOLUTE PRESSURE: is zero referenced against an absolute vacuum, so it is equal to gauge pressure minus atmospheric pressure. In order to make clear that it concerns absolute pressure an 'a' is added to the unit of measure, e.g.: mbara; PSla

GAUGE PRESSURE: is zero referenced against atmospheric pressure, so it is equal to absolute pressure plus atmospheric pressure. Negative signs are usually omitted. In order to make clear that it concerns gauge pressure 'g' is added to the unit of pressure, e.g.: mbarg; PSIg

DIFFERENTIAL PRESSURE: is the difference in pressure between two values

DEFINITIONS OF PRESSURE IN PROCESS INDUSTRY

Within the process industry different nominations of pressures are commonly used. The most relevant pressures for Diaphragm Seal Systems are the design pressure, the maximum working pressure, and the operating pressure.

MAXIMUM WORKING PRESSURE (MWP): is the highest pressure a device can withstand without bursting or failure in any way

The MWP is higher than any other pressure that can occur in process.

DESIGN PRESSURE: both the lowest and highest pressure that can occur in a given process specification

The minimum/maximum design pressure is reached when the process runs out of control and before the safety devices (e.g. pressure relief valves, rupture discs) come into service. Design pressures need to be taken into consideration during design phase to ensure mechanical integrity of the device when exposed to these design pressures. Proper functioning after exposure to the minimum/maximum design pressure is not required.

OPERATING PRESSURE:

- Minimum: the lowest pressure under which the process still runs stable
- Normal: the pressure under which the process runs optimally
- Maximum: the highest pressure under which the process still runs stable

Operating pressures need to be considered to ensure proper functioning of the device as such they are important for selecting the correct diaphragm seal design and fill fluid.

STATIC PRESSURE: the pressure at a nominated point in the process

Static pressure is commonly used to avoid ambiguity and to distinguish it from total pressure and dynamic pressure. Static pressure is identical to pressure and can be

either one of the above mentioned nominations of pressure. The static pressure is especially important in case of differential pressure measurement. E.g. pressure at high pressure (HP) side is 100,1 barg; pressure at low pressure (LP) side is 100 barg, then the differential pressure (dP) is 0,1 bar, and the value of the static pressure is 100 bar.

HYDROSTATIC PRESSURE: is the pressure exerted by a fluid column due to the force of gravity

With hydrostatic pressure measurement it is possible to measure level in vessels, tanks, reactors etc. This is one of the most common applications for Diaphragm Seals. Also the hydrostatic pressure can be used to measure changes in density.

A proper Diaphragm Seal selection is influenced by the above mentioned pressures of the process. Each diaphragm seal type has limitations according its construction or body material. For flanged connections an addendum is provided showing the maximum and minimum pressure/temperature ratings. Both flanged and threaded process connections have standard restrictions in withstanding pressure (EN1092-1, ASME B16.5, ANSI B1.20.1, ISO7005-1, ISO228-2, ISO10423, JIS B2220). The construction of the Diaphragm Seal however can also be a restrictive factor and is specified on the data sheets as the maximum working pressure of the specific Diaphragm Seal.

VACUUM

Care should be taken when specifying a Diaphragm Seal System for measuring with process pressure under vacuum.

FULL VACUUM: the absence of matter

While the Diaphragm Seals perform normally for most standard vacuum applications, as the pressure moves closer to a full vacuum acceptable reliability becomes more difficult to achieve. This is due to the fact that most fill fluids contain microscopic amounts of air or trapped gases, which tend to expand significantly as a pressure of absolute zero is approached. This expansion undermines one of the most important component factors of a seal system, that of absolutely constant fill fluid volume at any pressure. In order to overcome this

potential problem, the Badotherm filling technology allows for a complete degassing of the fill fluid, at a pressure of $< 1 \cdot 10^{-8}$ mbara in combination with the correct heating of the applied fill fluid.

Also, under vacuum process conditions, there is a potential risk that through a gasket or thread air is sucked in the system, with all possible consequences for the functioning of the Diaphragm Seal System. With Badotherm's full welded construction the measuring element has no gasket anymore to avoid any kind of leakage. Often vacuum occurs unintentionally for example during cleaning and fast cooling processes. To cover this often unknown and unaware presence of vacuum all Badotherm Diaphragm Seals are standard tested at 35 mbara even when no vacuum value is specified.

The presence of vacuum in process is a very important factor when selecting the Diaphragm Seal fill fluid and mounting the instrument. The relation between the vacuum value and the process temperature should be checked in the vapour pressure curves of the fill fluid to see if the fill fluid is suitable. When mounting the instrument for a vacuum application, the instrument should be placed below the (lowest) Diaphragm Seal to protect the instrument.

DIAPHRAGM SEAL PRESSURE SPECIFICATIONS

The size of the diaphragm defines the minimum pressure range that the Diaphragm Seal can handle. Apart from the diameter, the flexibility of the diaphragm is also related to the shape and number of convolutions, the material, and its thickness. Badotherm diaphragms have standard thickness of 75 μm . The dD dimensions mentioned are values for the active diameters of the diaphragms i.e. the outside diameter of the outer convolution. Badotherm Diaphragm Seals have a maximum static pressure effect of 0,25% of calibrated DP span on top of the standard differential pressure transmitter specifications with regard to static pressure effects. In general the total effect is $< 0,5\%$ of calibrated DP span.

The following table presents an overview of the diaphragm size and the related pressure characteristics:

MINIMUM PRESSURE RANGE OR SPAN

	DP transmitter (mbar)			GP/AP transmitter (mbar)				Pressure gauge (bar)						BDT13 (mbar)
	1m	5m	15m	Direct	1m	5m	15m	63mm		100mm		160mm		
Diaphragm size								Direct	5m	Direct	5m	Direct	5m	
17mm	-	-	-	100 bar	-	-	-	100	-	-	-	-	-	-
20mm	-	-	-	50 bar	-	-	-	100	100	-	-	-	-	-
23mm	-	-	-	4 bar	5 bar	6 bar	10 bar	6	25	-	-	-	-	-
32mm	-	-	-	2 bar	2.5 bar	3 bar	4 bar	2.5	10	25	25	100	100	-
44mm	200	400	400	1200	1500	1800	2100	1.6	6	2.5	4	4	25	-
51mm	100	200	200	800	1000	1200	1400	1	1.6	1.6	2.5	2.5	4	-
57mm	50	100	100	600	750	900	1050	0.6	1	1	1.6	1.6	2.5	-
72mm	25	50	50	200	250	300	350	0.6	0.6	0.6	0.6	0.6	0.6	-
81mm	10	20	20	80	100	120	140	0.6	0.6	0.6	0.6	0.6	0.6	100

Notes:

- Minimum pressure ranges are only related to the diaphragm sizes. The pressure range of the transmitter or pressure gauge, and the capillary diameter should be adjusted accordingly.
- DP, GP & AP transmitter sensor diaphragm should be equal or smaller than seal diaphragm size.
- DP transmitter values applicable for double sided diaphragm seals.
- Pressure gauge dimensions refer to the internal size.

Testing variables:

- AISI 316(L) diaphragm material.
- Transmitter volume is average of various transmitters brands.
- Reference temperature 20°C.
- Capillary inside diameter 2mm (1mm for pressure gauges).
- Fill fluid BSO-22.

MAXIMUM PRESSURE

	DP transmitter (mbar)	GP/AP transmitter (mbar)	Pressure gauge (bar)						BDT13 (bar)
			63mm		100mm		160mm		
Diaphragm size			Direct	5m	Direct	5m	Direct	5m	
17mm	Limited to instrument or Diaphragm Seal pressure rating	Limited to instrument or Diaphragm Seal pressure rating	700	140	-	-	-	-	-
20mm			1000	250	-	-	-	-	-
23mm			1600	400	-	-	-	-	-
32mm			1600	1400	1400	540	1000	340	-
44mm			1600	1600	1600	1600	1400	1400	-
51mm			1600	1600	1600	1600	1600	1600	-
57mm			1600	1600	1600	1600	1600	1600	-
72mm			1600	1600	1600	1600	1600	1600	-
81mm			1600	1600	1600	1600	1600	1600	25

Notes:

- Maximum pressure ranges are only related to the diaphragm sizes. The pressure range of the transmitter or pressure gauge, flange rating and the capillary diameter should be adjusted accordingly.
- Pressure gauge dimensions refer to the internal size.

Testing variables:

- AISI 316(L) diaphragm material.
- Reference temperature 20°C.
- Capillary inside diameter 1mm.
- Fill fluid BSO-22.

INTRODUCTION

Temperature expresses the average energy of motion of particles in matter. A good explanation can be made with water: when water is solid (ice) the particles (H₂O molecules) are not in motion and the temperature is thus low (cold). When fluid the H₂O molecules move faster and the temperature becomes higher. When the H₂O molecules move that fast that they release themselves from the fluid, steam is formed and the temperature is high. The motion of particles in matter is also influenced by the pressure exerted on the matter. In the example, water boils at 100°C at atmospheric pressure (101,325 kPa); at absolute vacuum it boils at 0°C. This combined effect of pressure and temperature exists for all fluids and is as such a predominant factor for the selection of the Diaphragm Seal fill fluid.

The common units of measure for temperature are: Kelvin, Celsius, and Fahrenheit. The relation between these units is presented in the table below:

	Celsius	Kelvin	Fahrenheit
Celsius	-	$K=C + 273.15$	$F=C \times 1.8 + 32$
Kelvin	$C=K-273.15$	-	$F=K \times 1.8 - 459.67$
Fahrenheit	$C=(F-32)/1.8$	$K=(F+459.67)/1.8$	-

DEFINITIONS OF TEMPERATURE IN PROCESS

INDUSTRY

Within the process industry, several temperatures are defined:

AMBIENT TEMPERATURE: is the temperature of the surroundings

When a Diaphragm Seal System is situated outdoors, the ambient temperature can become a very important factor for the functionality of the Diaphragm Seal System. Ambient temperatures can range from extremely high (>60°C e.g. in desert sun) to low (<-40°C, e.g. off-shore wind). Ambient temperatures should be specified with a minimum and maximum value, e.g. -10/+35°C would be a general specification for the Netherlands.

Similar to process pressures, process temperatures are specified with following denominations:

DESIGN TEMPERATURE: both the lowest and highest temperature that can occur in a given process specification

The design temperature is reached when the process runs out of control. Design temperatures need to be taken into consideration during design phase to ensure mechanical integrity of the device when exposed to these design temperatures. Proper functioning after this exposure is not required.

OPERATING TEMPERATURE:

- Minimum: the lowest temperature under which the process still runs stable
- Normal: the temperature under which the process runs optimally
- Maximum: the highest temperature under which the process still runs stable

Operating temperatures need to be considered to ensure proper functioning of the device and as such they are important to select the correct Diaphragm Seal design and fill fluid. The device will operate effectively within a specified operating temperature range which varies based on the device function and application context, and ranges from the minimum operating temperature to the maximum operating temperature (or peak operating temperature). Outside of this range, the device may fail. Each Diaphragm Seal has limitations according its construction or base material. For the flange connection a guide is provided, showing the maximum and minimum temperature ratings. This guide also details limitations on the flanges concerning at what pressure they can be used at specific temperatures. The maximum operating temperature is limited by the sealed system component with the lowest maximum temperature. The limiting component may be, but is not limited to, any one of the following: housing material, diaphragm material, gasket or o-ring material, or fill fluid.

TEMPERATURE EFFECTS

Changes in the volume of the Diaphragm Seal System can be caused by changes in volume and density of the fluid in the system and occur when the fill fluid expands or contracts due to fluctuations of the process and/or ambient temperatures. This change in fill volume drives

a change in the internal pressure of the Diaphragm Seal System. This is called the temperature effect.

There are 3 different influences that can be distinguished:

- **Process temperature:** the process temperature has effect on the Diaphragm Seal system and influences, in combination with the lowest process pressure, the selection of the fill fluid.
- **Ambient temperature:** Differences in ambient temperature have an effect on the viscosity and on the density of the fill fluid. The change in viscosity has a direct effect on the response time of the Diaphragm Seal System. The change in density creates a mounting effect in case of a vertical height difference which results in a zero-point deviation of the Diaphragm Seal System.
- **Delta T in DP measurement:** Temperature effects can cause a difference in density or viscosity between the HP side and LP side of the Diaphragm Seal System.

CALCULATED TEMPERATURE EFFECTS

The Diaphragm Seal System’s volume consists of three components: Diaphragm Seal chamber volume, capillary volume, and the pressure instrument volume. The table below presents the temperature effect in mbar for each of the components. The values for each component in the table need to be added to arrive at the total temperature effect for the Diaphragm Seal System.

DP transmitter with two Diaphragm Seals

Diaphragm Size	Transmitter (mbar)	Seal (mbar)	Capillary (mbar/mtr)
44mm	0.62	0.91	1.62
51mm	0.10	0.76	1.19
57mm	0.02	0.24	0.41
72mm	0.01	0.11	0.12
81mm	0.01	0.08	0.07

Temperature effect per 10°C

GP/AP transmitter with Diaphragm Seal

Diaphragm Size	Transmitter (mbar)	Seal (mbar)	Capillary (mbar/mtr)
17mm	300	300	1600
20mm	150	150	800
23mm	85	84	409
32mm	20	17	17
44mm	3.11	4.56	8.10
51mm	0.52	3.79	5.95
57mm	0.12	1.22	2.04
72mm	0.03	0.53	0.62
81mm	0.02	0.39	0.35
LGP	0.02	0.09	0.03

Temperature effect per 10°C

Pressure Gauge with Diaphragm Seal below 60 bar

Diaphragm size	Pressure Gauge (mbar)			Seal (mbar)	Capillary (mbar/mtr)
	63mm	100mm	160mm		
32mm	63	256	-	17	17
44mm	13	52	90	4.6	8.1
57mm	4.0	15	25	3.8	2.0
72mm	1.0	4.0	8.0	0.5	0.6
81mm	0.4	2.0	3.0	0.4	0.4

Temperature effect per 10°C

Pressure Gauge with Diaphragm Seal above 60 bar

Diaphragm size	Pressure Gauge (mbar)			Seal (mbar)	Capillary (mbar/mtr)
	63mm	100mm	160mm		
32mm	32	128	-	17	70
44mm	6.5	26	45	4.6	8.1
57mm	2.0	7.5	13	3.8	2.0
72mm	0.5	2.0	8.0	0.5	0.6
81mm	0.2	1.0	3.0	0.4	0.4

Temperature effect per 10°C

Testing variables:

- Reference temperature 20°C
- Inside capillary diameter 2mm
- Diaphragm stainless steel AISI 316(L)
- Filling fluid is BSO-22
- Transmitter volume is an average of various transmitters brands
- Diaphragm Seal and instrument are at same height

EXAMPLE CALCULATION:

DP transmitter with two 3” seals (81mm diaphragm) and 5 meter capillary.

- Transmitter: 0.01 mbar
- Seal: 0.08 mbar
- Capillary: 0.35 mbar (5x0.07)
- **Worst case effect: 0.44 mbar / 10°C**

MINIMISING TEMPERATURE EFFECTS

Temperature effects can be minimised by using the following techniques:

- **Reduce the volume of the application:** This can be done with reducing the capillary internal diameter (ID). However, reducing the capillary ID increases the response time for the application and in this a balance needs to be found. Badotherm standardly uses 2mm as inside diameter of the capillary. Switching to capillary with ID of 1 mm will increase the response time with a factor 16. Capillary with 1mm inside diameter is advised for gauge pressure applications with a range above 100 barg. It is also important to minimise the volume of fill fluid contained in the pressure instrument to a minimum. This can be done by replacing the standard process covers of a transmitter by special designed low volume covers, or to use pressure gauge with a reduced volume.
- **Specify the shortest possible capillary lengths for the application:** it is understandable that for interchangeable reasons the capillary lengths for all LT tags in a project are specified with the same length. It is advised that capillary lengths should be calculated on a tag by tag basis to define the shortest possible length for each tag. Too long capillaries will result in unacceptable response times and/or too high temperature influences with all consequences for the reliability of the measurement.
- **Cold temperature application:** there are processes where, due to a system of both low ambient and process temperatures, the contraction of fill fluid is as such that the diaphragm runs against the diaphragm chamber and transfer of pressure is no longer possible. A solution for these situations is a so-called 'supplementary fill' which allows for pressure transfer even when the fill fluid heavily contracts.
- **Insulation of Diaphragm Seal System:** in cases where both capillaries and Diaphragm Seals are exposed to severe outdoor conditions, insulating them will reduce ambient temperature effects considerably. Also in those cases where the capillary of one leg of a DP system is in the sun and the other leg in the shadow insulating them will result in the same or similar ambient temperature at both legs and minimises ambient temperature effects.
- **Tracing of capillaries:** this will reduce ambient temperature effects close to zero. Often tracing is considered expensive and requires intensive maintenance. However, a new development is that Badotherm is working together with O'Brien to include the product Tracepak around capillary lines already at the time of assembly of the Diaphragm Seal system.
- **High temperature process and temperature reducers:** in those processes with high temperatures (> 200°C) and where distant mounting by means of capillary is not possible, a temperature reducer (TR) can be foreseen between instrument and Diaphragm Seal. A temperature reducer reduces process temperatures to a value < 100°C at the instrument side.
- **Temperature compensator:** when the specifications of the process prescribe the use of a fill fluid with high viscosity this might result in unacceptable response times. A temperature compensator (TC) is developed to overcome this problem. By using the high viscous fill fluid in the part between seal diaphragm and TC, the fluid keeps a relative high temperature resulting in a low viscosity; after the TC a standard fill fluid with low viscosity is used resulting in an acceptable overall response time.
- **Process simulation:** Badotherm offers the possibility of a full process simulation. The Diaphragm Seal System is simultaneously subjected to: process temperature, ambient temperature, and static process pressure. Their respective influences on the calibrated (DP) span are recorded. This results in a fingerprint for this specific Diaphragm Seal System and the influences can be incorporated into the DCS to compensate for the effects. The result is a pressure (level) measurement with enhanced accuracy.
- **LGP solution:** is designed for Low Gauge Pressure measurement and eliminates temperature and mounting influences. Test results obtained by measuring low gauge pressures with a standard Diaphragm Seal and with the LGP, showed that the minimum range reduces from 80 mbar for a standard seal to only 10 mbar with the LGP. Similarly the ambient temperature effect reduces from 0.4 mbar per 10°C to 0.03 mbar, while the process temperature effect reduces from 0.39 to 0.09 mbar.

INTRODUCTION

Instruments with Diaphragm Seals can be mounted in various positions. In a differential pressure measurement the instrument can be mounted between the nozzles, but the instrument can also be mounted above the highest or below the lowest nozzle. Also in a gauge pressure measurement the instrument can be mounted in various positions compared to the Diaphragm Seal.

The mounting of the instrument is important to ensure the best possible measurement in the given circumstances. The specific gravity of the vertical fill fluid column between the instrument and the Diaphragm Seal is influenced by the ambient temperature deviation. These influences create a pressure variation within the Diaphragm Seal System. This is called the mounting effect.

SHIFT IN ZERO POINT

When the exact mounting details of the transmitter and the Diaphragm Seal are not known at calibration, the span is set from zero to the required value (e.g. 0-400 mbar). When mounting the Diaphragm Seal System in the field, the zero can shift depending on how it is mounted. This is caused by the gravity effect after installation. This shift can be zero suppression or zero elevation.

ZERO SUPPRESSION:

the factory calibrated zero is shifted above zero after installation (e.g. 150 + 550 mbar)

ZERO ELEVATION:

the factory calibrated zero is shifted below zero after installation (e.g. -390 + 10 mbar)

The shift in zero point can be calculated with the density of the Badotherm fill fluid, the height difference of the installed application, and the gravity. The shift in zero point is important to know prior to installation because the shift must remain within the limits of the transmitter range. If the zero shift is outside the limits of the transmitter range, the transmitter will fail to measure.

Badotherm Diaphragm Seals have a minimum working pressure of 1 mbara, depending on the filling fluid. Please consider the minimum static or working pressure of the pressure instrument that is mentioned in the brand specific documentation.

DIFFERENTIAL PRESSURE APPLICATIONS

Differential pressure applications can be used for various purposes: differential pressure, level, flow, density, and interface measurements. There are three different mounting styles for level to be recognised, depending on the position of the instrument compared to the Diaphragm Seal.

- **DP STYLE 1:** instrument between the Diaphragm Seals
- **DP STYLE 2:** instrument below the Diaphragm Seals
- **DP STYLE 3:** instrument above the Diaphragm Seals

DP Style 1: instrument between the Diaphragm Seals

DP Style 2: instrument below the Diaphragm Seals

- Ease of installation
- Accessibility of the instrument: reading of local display and maintenance
- Obstacles that do not allow to place the instrument elsewhere

However, the process conditions should be considered first whilst selecting one of the mounting styles. The following example illustrates this.

Suppose DP Style 3 has been selected because the vessel is positioned below the walking grid ($H_1=360\text{cm}$). The fill fluid (density $1,020\text{ kg/m}^3$) column in the capillary that connects the lowest seal (P_2) with the DP instrument, represents a pressure of ($p=h*\rho*g$): $0,360*1,020*9.81 = 360,2\text{ mbar}$. This hydrostatic pressure is sensed at the DP instrument as a negative pressure, $-360,2\text{ mbar}$. When in this application the minimum operating pressure is as low as -800 mbar (200 mbar), the selected mounting by style 3 will damage the Diaphragm Seal System: $-360,2 - 800\text{ mbar} = -1160,2\text{ mbar}$. This implies a pressure below absolute zero which is impossible. This will either damage the diaphragm of the seal or the diaphragm of the DP instrument. Also, the fill fluid can be damaged because it is pushed over the limits of its vapour pressure.

DP Style 3: instrument above the Diaphragm Seals

In this example DP Style 2 would have been the better option. The transmitter is then placed below the vessel ($H=160\text{CM}$) and the hydrostatic pressure is then: $0,160*1,020*9.81 = 160,1\text{ mbar}$. This is sensed at the DP instrument as a positive pressure $+160,1\text{ mbar}$. With the minimum operating pressure of -800 mbar , it would result in a pressure at the instrument of $-800 + 160,1 = -639,9\text{ mbar}$. This is well above absolute zero, and thus the instrument and Diaphragm Seal System will function properly.

Each style has specific advantages, limitations, and considerations that should be taken into account. DP Styles 1 and 3 only allows limited vacuum and DP Style 2 allows for full vacuum (1mbar), when 'H' is at least 50 cm . The selection of one of the above indicated mounting styles is often driven by:

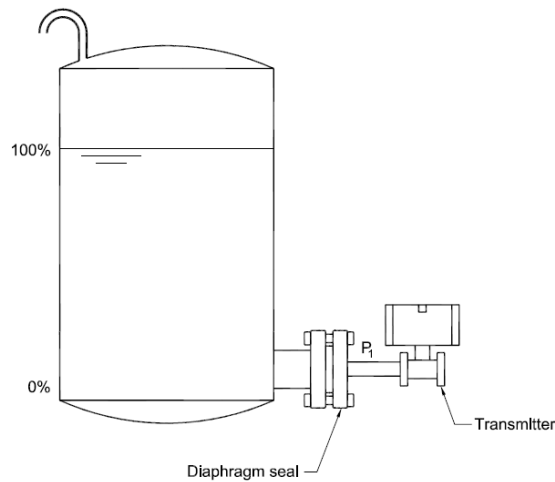

GAUGE PRESSURE APPLICATIONS

Gauge pressure applications can be used for pressure, level, and density measurement. Also for this application there are three different styles to be recognised depending on the position of the instrument compared to the Diaphragm Seal.

- **GP STYLE 1:** instrument equal to the Diaphragm Seal
- **GP STYLE 2:** instrument below the Diaphragm Seal
- **GP STYLE 3:** instrument above the Diaphragm Seal

The effect of the mounting on a GP instrument is similar as described for the DP instrument. When an instrument is placed above the seal, it will sense this as a negative pressure and that pressure, in combination with the minimum operating pressure, should not exceed a value below absolute zero. The Diaphragm Seal System would be damaged in a similar way as described for DP applications.

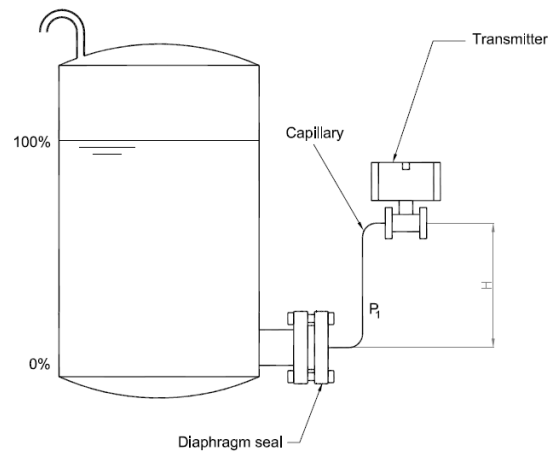

GP Style 1: instrument equal to the Diaphragm Seal

GP Style 2: instrument below the Diaphragm Seal

GP Style 3: instrument above the Diaphragm Seal

ABSOLUTE PRESSURE APPLICATIONS

Absolute pressure applications are only used to measure pressure. For this application there can be also three different styles recognised depending on the position of the instrument compared to the Diaphragm Seal.

- **AP STYLE 1:** instrument equal to the Diaphragm Seal
- **AP STYLE 2:** instrument below the Diaphragm Seal
- **AP STYLE 3:** instrument above the Diaphragm Seal

For absolute pressure measurement the instrument should be mounted below the diaphragm seal in order to protect the instrument at all possible conditions. This is presented in AP Style 2. If for example $H=50\text{cm}$ the pressure on the instrument is already above 50 mbar. With this mounting style the instrument has additional protection before it reaches absolute zero. AP Style 1 is also possible, but not preferred as there is no additional protection so it is possible to reach the absolute zero and damage the application.

AP Style 1: instrument equal to the Diaphragm Seal

AP Style 2: instrument below to the Diaphragm Seal

Mounting the instrument above the Diaphragm Seal (AP Style 3) will damage the Diaphragm Seal System in a similar way as described under DP applications. Care should be taken, when an instrument is direct mounted on the Diaphragm Seal and installed as shown in AP Style 3. As a standard, Badotherm uses a distance tube of 80 mm. With a silicon BSO fill fluid, this will create a negative pressure of approximately 8 mbar at the pressure sensor. When the absolute pressure runs below 8 mbara, the Diaphragm Seal or instrument will be damaged.

AP Style 3: instrument above to the Diaphragm Seal

DIAPHRAGM SEALS AND WET LEGS

A wet leg is made with tubing mounted directly to the transmitter and is filled with process medium. Diaphragm Seal Systems offer significant installation flexibility and maintenance advantages over wet leg systems. Diaphragm Seals make it easier to maintain the fluid between the tap and the transmitter, especially on the reference or low pressure side. In vacuum systems, a closed seal system, rather than an open wet leg, maintains a constant height for the low side reference. The Diaphragm Seal System does not need to be refilled or drained. They are also not vulnerable to plugging or freezing and they are easier to control than wet leg systems.

**BALANCED SYSTEM**

A balanced system means that the volume of the Diaphragm Seal System is equal at the HP and LP side of the DP measurement. This can be obtained by ensuring that the fill volume in the Diaphragm Seal and the capillary lengths are similar at both sides. An unbalanced system can be equipped with two different sized diaphragms and/or with using two different lengths of capillary. This results in a larger volume of fill fluid on one side compared to the other side.

A balanced Diaphragm Seal System is preferred above an unbalanced system because it reduces or avoids the effect mentioned next:

- **Ambient temperature effects:** as a result of ambient temperature changes balanced systems will have equal expansion and/or contraction of fill fluid. As both sides are equal the effect on the DP transmitter will be zero or close to zero. Unbalanced systems have a different expansion and/or contraction of fill fluid on either side due to ambient temperature changes. This results in a different pressure build up (expansion) or drop (contraction) which negatively influences the accuracy of the overall measurement.
- **Process temperatures effects:** For applications with an elevated process temperature (>65°C) the effect of an unbalanced system can be considerable. For example there is an unbalanced system with a direct mounted Diaphragm Seal to the HP side and a capillary mounted to the LP side. The heat transfer from the process temperature to the direct mount on the HP side of the instrument will be higher than to capillary mount on the LP side of instrument. This results in a different pressure build up (expansion) which negatively influences the accuracy of the overall measurement.
- **Static pressure effects:** In case of fluctuating static pressures unbalanced systems can become unstable because the static pressure will be transferred faster to the side with the lowest volume.

REDUCTION OF MEASUREMENT ERRORS

There are different ways to minimise the measurement errors of the Diaphragm Seal System:

- Keep capillary lengths as short as possible
- Use capillaries of the same length on both taps when measuring differential pressure
- Use diaphragms with the same diameter
- Never mount seals and capillaries in direct sunlight
- Ensure that both capillaries experience the same temperature. For instance, avoid installing one capillary in a shady area and the other in the sun

OVERVIEW OF TYPES OF DIAPHRAGM SEALS

Once performance needs, process conditions, and installation requirements are known, the individual seal components can be selected. The following pages describe the available seal types, the system assembly options,

and fill fluid characteristics. Badotherm offers a complete variety of Diaphragm Seals to meet application needs.

FLANGED DIAPHRAGM SEALS

These types of diaphragm seals are designed for either direct mounting on the process flange or by clamping the seal between process flange and a cover flange.

They are available in all kinds of international flange standards, ASME B16.5, EN1092-1, API 6A ISO 10423 or JIS B2220.

BF

- 30 The BF construction has a seal body that is made of a blind flange. The weld of the diaphragm to the seal body is a wetted part and therefore diaphragm materials are mostly chosen the same as the flange material.

BRF

- 35 The BRF construction has a seal body that is made of a blind flange and is designed to obtain a diaphragm seal with full wetted parts in exotic materials. With Badotherm unique resistance weld technology, a stainless steel body (non-wetted) has its wetted parts (diaphragm and raised face area) covered by sheet material in the required exotic material.

BC

- 38 The BC construction has a seal body that is made of bar stock or forged material. The weld of the diaphragm to the seal body is a wetted part and therefore diaphragm materials are mostly chosen the same as the flange material. Its pressure rating is defined by the back-up flange and as such it can be used for all pressure ratings in RF or type B1 facings.

BRC

- 41 The BRC construction is designed to obtain a diaphragm seal with full wetted parts in exotic materials. With Badotherm unique resistance weld technology, a stainless steel body (non-wetted), has its wetted parts (diaphragm and raised face area) covered by sheet material in the required exotic material. Its pressure rating is defined by the back-up flange and as such it can be used for all pressure ratings in RF or type B1 facings.

EXT

- 43 EXT (extended) construction is typically used when the diaphragm needs to be flush with the vessel wall or where insulation layers need to be passed. The weld of the diaphragm to the seal body is a wetted part and therefore diaphragm materials are mostly chosen the same as the flange material.

USF

- 46 The USF construction is designed for those applications where the existing process connection is too small to use a flush diaphragm seal. The USF consists of an upper and lower housing. The lower housing creates the transition from the diaphragm size to the actual small process connection.

USLF

- 48 The USLF construction has a larger diaphragm with a better performance than the USF and is designed for those applications where the existing process connection is too small to use a flush diaphragm seal. The lower housing creates the transition from the diaphragm size to the actual small process connection.

FLANGED SLIP ON (FSO) DIAPHRAGM SEALS

The FSO construction is used when special flange grades are required and keep the use of exotic material limited

to the wetted parts, but only for groove type gasket facings.

FSO-BF

50 The FSO-BF construction has a seal body that is made of bar stock or forged material. The weld between the seal body and the diaphragm is a wetted part and therefore diaphragm materials are mostly chosen the same as the body material. The FSO-BF is recommended when special body or flange material grades are required.

FSO-BRF

55 The FSO-BRF construction is designed to obtain a diaphragm seal with full wetted parts in exotic materials. With Badotherm unique resistance weld technology, a stainless steel body (non-wetted), has its wetted parts (diaphragm and raised face portion) covered by sheet material in the required exotic material. FSO-BRF is recommended when special flange grades are required.

FSO-EXT

58 FSO-EXT is typically used in when the diaphragm needs to be flush with the vessel wall or where insulation layers need to be passed. The FSO-EXT is recommended when extended seals are required fully in exotic materials and/or when special grade flanges are required.

THREADED DIAPHRAGM SEALS

These types of diaphragm seals are designed for direct mounting on the threaded process connection. They are

available in all kind of international thread standards, NPT, BSP, and metric.

UST

60 The UST construction is designed for those situations where the existing threaded process connection is too small to use a flush diaphragm seal. The upper part is the seal part with a diaphragm size that allows for proper measurement. The lower housing enables the transition to the actual small process connection.

USLT

62 The USLT construction has a larger diaphragm with better performance as the UST and is designed for those applications where the existing process connection is too small to use a flush diaphragm seal. The upper part is the seal part with a diaphragm size that allows for proper measurement. The lower housing enables the transition to the actual small process connection.

ECx

64 The ECx is a welded type construction and designed for those applications where the process conditions are such that direct mounting of the instrument cannot be done. Applications are viscous media, waste water treatment, or when special wetted parts materials for pressure gauges are required. ECx is typically used in combination with pressure gauges.

PS

67 The PS construction is designed for those applications where the process is very viscous and/or containing parts that might obstruct the process connection of the instrument. Typical applications can be found in pulp & paper industries and waste water treatment. The PS is a single part construction.

SANITARY DIAPHRAGM SEALS

Sanitary seals are designed for pressure, level and flow measurements in food & beverage, and pharmaceutical industries where the formation of bacteria needs to be prevented by reducing or eliminating blind spaces where

process product could remain and thus creating impurities, bacteria by e.g. fermentation. As such these seals allow for easy cleaning by means of either threaded or clamped quick couplings.

SA

69 Sanitary seals are designed for food and pharmaceutical industries where the formation of bacteria needs to be prevented by reducing or eliminating blind spaces where process product could remain and thus creating impurities, bacteria by e.g. fermentation. These seals are standard in stainless steel AISI 316(L). Common connections are DIN 11851 / SMS 1145 and TRI-CLAMP ISO – 2852/ DN 32676.

ILS

74 ILS is typically used in combination with pressure transmitters for pressure measurement (≥ 2 barg) applications. Its pressure rating is defined by the connections between which it is clamped and as such it can be used for all pressure ratings.

SPECIAL DIAPHRAGM SEALS

Some applications require non-standard diaphragm seals. Badotherm has developed several Diaphragm Seals seal that can withstand extreme process condi-

tions, or diaphragm seals that require specially designed connections.

HTDS

76 The HTDS is a Diaphragm Seal that can meet process temperatures up to 600°C. To enable a proper functioning of the Diaphragm Seal at these extreme process temperatures a revolutionary new design and principle is used. The novelty of the design is as such that Badotherm has a Patent on the High Temperature Diaphragm Seal (HTDS).

BHS

79 Badotherm Hub seal is a special design based on high pressure clamp so called hub connectors such as Destec® or Galperti®. These type of connectors are designed for high pressure applications (>400 bar) where standard flanges cannot be used or only with extreme heavy weight, since another advantage of the Hub connector is the relative small design with a far lower load on the process installation.

SJ

81 SJ is typically used in those applications where the diaphragm needs to be flush with the pipe wall. This can be obtained by either mounting the SJ seal part in a saddle type that is welded on top of the piping or in a flow through block that can be welded into the piping or mounted by means of flanges. Typical applications are pressure measurements of highly viscous media.

BHP

84 The BHP construction is designed for those applications the process pressure is very high. The construction is executed with a stainless steel sensing element welded in bar stock material which is designed to withstand these high pressures up to 4000 bar.

FLUSH RINGS, FLUSH FLANGES, AND REDUCER FLANGES

The flushing flange or ring is used for flushing solution combined with diaphragm seals. This type of flushing flange or ring is clamped between process nozzle and diaphragm seal. The reducer flange is used to mount a

larger diaphragm seal to a smaller process connection. This type of reducer flange is bolted between process nozzle and diaphragm seal.

FLUSH FLANGE		104	Flushing flange is used for flushing solution combined with diaphragm seals. This type of flushing ring is clamped between process nozzle and diaphragm seal and aligned by the exact same bolt holes as the process nozzle and the diaphragm seal. The flushing flange can be combined with the BF and BRF seal.
FLUSH RING		107	Flushing ring is used for flushing solution combined with diaphragm seals. This type of flushing ring is clamped between process nozzle and diaphragm seal. The flushing ring can be combined with the BF and BRF seal as well as the BC and BRC type.
REDUCER FLANGE		111	Reducer flange is used to mount a larger diaphragm seal to a smaller process connection. This type of reducer flange is bolted between process nozzle and diaphragm seal. Eccentric reducer flanges can be supplied to prevent process media remaining in the reducer ring when mounted in vertical position. The reducer flange can be combined with the BF and BRF seal as well as the BC and BRC type.
FLUSH & VALVE		104-111	Flush rings or flanges can be supplied with valves fitted or welded, and tested.

DIAPHRAGM SEAL ACCESSORIES

Diaphragm Seal Accessories are carefully designed to optimise the use of the Diaphragm Seal in your process

conditions, or to ease the installation and protect it against damaging during installation.

SUPPORT HANDLES		113	Support handles are available for 2” and 3” Diaphragm Seals and flush flanges to assist in easy handling during installation.
SUPPORT TUBE		113	Heavy duty support tube is available for all capillary connections on Diaphragm Seals and provides additional protection and increases the durability.
TEMPERATURE REDUCER		114	Temperature reducer is used to protect the instrument from high process temperatures and is used in combination with direct mounted Diaphragm Seals.
TEMPERATURE COMPENSATOR		114	Temperature compensator is used to lower the response time in combination with long capillaries and high or low temperatures.

The BF construction has a seal body that is made of a blind flange. The weld of the diaphragm to the seal body is a wetted part and therefore diaphragm materials are mostly chosen the same as the flange material. The BF is typically used in combination with (differential) pressure transmitters for applications such as level, flow and (absolute) pressure measurement.

The BRF construction has a seal body that is made of a blind flange and is designed to obtain a diaphragm seal with full wetted parts in exotic materials. With Badotherm unique resistance weld technology, a stainless steel body (non-wetted) has its wetted parts (diaphragm and raised face area) covered by sheet material in the required exotic material. This is more economic than producing the full body in exotic material. BRF is typically used in combination with (differential) pressure transmitters for applications such as level, flow and (absolute) pressure measurement.

The BC construction has a seal body that is made of bar stock or forged material. The weld of the diaphragm to the seal body is a wetted part and therefore diaphragm materials are mostly chosen the same as the flange material. Its pressure rating is defined by the back-up flange and as such it can be used for all pressure ratings in RF or type B1 facings. An extra feature of BC type seal is that it can be equipped with the so-called LGP module, which allows for Low Gauge Pressure measurement with temperature influences reduced with factor 10.

The BRC construction is designed to obtain a diaphragm seal with full wetted parts in exotic materials. With Badotherm’s unique resistance weld technology, a stainless steel body (non wetted), has its wetted parts (diaphragm and raised face area) covered by sheet material in the required exotic material. This is a more economical solution than producing the full body in exotic material. BRC is typically used in combination with (differential) pressure transmitters for applications such as level, flow and (absolute) pressure measurement. Its pressure rating is defined by the back-up flange mounted by the end-user, as such it can be used for all pressure ratings in RF or type B1 facing.

The USF construction is designed for those applications where the existing process connection is too small to use a flush diaphragm seal. The USF consists of an upper and lower housing. The lower housing creates the transition from the diaphragm size to the actual small process connection. USF is typically used in combination with (differential) pressure transmitters for applications such as level, flow and (absolute) pressure measurement; also the USF is often combined with pressure gauges.

The USLF construction is designed for those applications where the existing process connection is too small to use a flush diaphragm seal. The USLF consists of an upper and lower housing, the upper is the actual seal part with a diaphragm size that allows for measurement of low ranges (10 mbar 2 seals attached (dP); 80 mbar single seal attached). The lower housing creates the transition from the diaphragm size to the smaller process connection. USLF is typically used in combination with (differential) pressure transmitters for applications such as level, flow and (absolute) pressure measurement.

The FSO-BF construction has a seal body that is made of bar stock or forged material. The weld between the seal body and the diaphragm is a wetted part and therefore diaphragm materials are mostly chosen the same as the body material. The FSO-BF is recommended when special body or flange material grades are required. FSO-BF is typically used in combination with (differential) pressure transmitters for applications such as level, flow and (absolute) pressure measurement.

The FSO-BRF construction is designed to obtain a diaphragm seal with full wetted parts in exotic materials. With Badotherm’s unique resistance weld technology, a stainless steel body (non-wetted) has its wetted parts (diaphragm and raised face portion) covered by sheet material in the required exotic material. This is far more economic than producing the full flange in exotic material. FSO-BRF is typically used in combination with (differential) pressure transmitters for applications such as level, flow and (absolute) pressure measurement.

The FSO-EXT is typically used in combination with (differential) pressure transmitters for level, flow and pressure measurement, in those applications where the diaphragm need to be flush with the vessel wall or where insulation layers need to be passed. The FSO-EXT is recommended when extended seals are required fully in exotic materials and/or when special grade flanges are required.

The UST construction is designed for those applications where the existing threaded process connection is too small to use a flush diaphragm seal. The UST consists of an upper and lower housing, the upper is the actual seal part with a diaphragm size that allows for measurement of relatively low ranges (200 mbar 2 seals attached (dP); 800 mbar single seal attached). The lower housing creates the transition from the diaphragm size to the actual small process connection. UST is typically used in combination with (differential) pressure transmitters for applications such as level, flow and pressure measurement; also the UST is often combined with pressure gauges.

The ECx is a complete welded construction and designed for those applications where the process conditions are such that direct mounting of the instrument cannot be done. Applications are aggressive media, waste water treatment, or when special wetted parts materials for pressure gauges are required. ECx is typically used in combination with pressure gauges.

The PS construction is designed for those applications where the process is very viscous and/or containing parts that might obstruct the process connection of the instrument. Typical applications can be found in pulp & paper industries and waste water treatment. The PS is a single part construction. PS is typically used in combination with pressure transmitters and gauges for pressure measurement.

Badotherm sanitary seals are designed for pressure, level and flow measurements in food & beverage and pharmaceutical industries where the formation of bacteria needs to be prevented by reducing or eliminating blind spaces where process product could remain and thus creating impurities, bacteria by e.g. fermentation. As such these seals allow for easy cleaning by means of either threaded or clamp quick couplings. These seals are standard in stainless steel AISI 316(L). All these seals and fill fluid are suitable for CIP (Cleaning In Process) applications. Other aseptic flanged sanitary connections are available on request.

Badotherm has developed a Diaphragm Seal that can measure pressure with process temperatures up to 600°C. To enable a proper functioning of the Diaphragm Seal at these extreme process temperatures a revolutionary new design and principle is used. The novelty of the design is as such that Badotherm has a “Patent” on the High Temperature Diaphragm Seal (HTDS).

Typical applications for high temperature can be found in chemical process industry, petrochemical industry, and in the thermo-solar industry with molten salt.

Badotherm Hub seal is a special design based on high pressure clamp so called hub connectors such as Destec® or Galperti®. These type of connectors are designed for high pressure applications (>400 bar) where standard flanges cannot be used or only with extreme heavy weight, since another advantage of the Hub connector is the relative small design with a far lower load on the process installation. BHS seals can be used for either pressure measurement or differential pressure measurement (level, flow) where high static pressure occurs. The BHS can be produced with an internal diaphragm (smaller hub sizes) or a flush diaphragm (larger hub sizes), this depends on the specific application.

SJ is typically used in combination with pressure transmitters for pressure measurement, in those applications where the diaphragm need to be flush with the pipe wall. This can be obtained by either mounting the SJ seal part in a saddle type that is welded on top of the piping or in a flow through block that can be welded into the piping or mounted by means of flanges. Typical applications are pressure and flow measurements of highly viscous media.

The selection of a fill fluid for a diaphragm seal application requires a careful review of the application conditions. The fill fluid characteristics determine to a large extent the diaphragm seal system performance in terms of response time and temperature effect. Several fill fluid characteristics need to be taken into account to make the appropriate selection of the fill fluid.

At first the **type of fill fluid** is important as it should be compatible with the process medium. The most commonly used are Silicone or Inert based fluids, but also other specific types are used; all with specifications and characteristics to match different conditions. The **operating temperature** of the fill fluid is the second im-

portant factor for selection. The application temperature should remain between the limits to guarantee proper functioning of the application. All fill fluids expand or contract with changes in temperature and this is referred to as the diaphragm seal temperature effect. The fluid **viscosity and density** have an effect on the response time of the application. A more viscous fill fluid will result in a longer response time and a fill fluid with a higher density will have an increased mounting effect. The **vapour pressure** curve shows if the selected fill fluid is suitable for the minimal process pressures in combination with the desired process temperatures. This is especially important for vacuum applications.

OPERATING TEMPERATURE GRAPH (°C)

BSO-02 is a silicone fill fluid designed for high temperature applications. Its vapour pressures are relatively elevated at higher temperatures and its low viscosity results in excellent performance with regard to response times.

- For high temperature applications
- This fluid is not approved for food or pharmaceutical applications

VAPOUR PRESSURE RESULTS

BSO-02

BSO-03 is an inert CTFE fill fluid. Its very low viscosity allows for excellent response times. This fluid has a reported freezing point of -93°C, but the temperature limit is set at a higher temperature to allow the Diaphragm Seal System to function properly.

- Typically used for low temperature applications
- Used in silicon free environments
- Can be used for chlorine and oxygen applications
- Can be used as secondary fill for Temperature Compensator
- This fluid is not approved for food or pharmaceutical applications

SPECIFICATIONS

OPERATING TEMPERATURE	DESIGN TEMPERATURE	FREEZING POINT TEMPERATURE
-80/+100 °C	+100°C	-93°C
TYPE	VISCOSITY	DENSITY
Inert	2.4 cSt	1.84 kg/dm ³

Note: viscosity and density at 25°C

VAPOUR PRESSURE RESULTS

BSO-03

BSO-06 is an inert CTFE fill fluid. This fluid has a reported freezing point of -40°C, but the temperature limit is set at a higher temperature to allow the Diaphragm Seal System to function properly.

- Typically used in silicon free environments
- Can be used for chlorine and oxygen applications
- This fluid is not approved for food or pharmaceutical applications

SPECIFICATIONS

OPERATING TEMPERATURE	DESIGN TEMPERATURE	FREEZING POINT TEMPERATURE
0/+200 °C	+200°C	-40°C
TYPE	VISCOSITY	DENSITY
Inert	40.0 cSt	1.92 kg/dm ³

Note: viscosity and density at 25°C

VAPOUR PRESSURE RESULTS

BSO-06

BSO-18 is a silicone fill fluid designed as a fluid for diffusion pumps for applications where high vacuum in combination with elevated temperatures are present. In cold outdoor applications its relative high viscosity might result in long response times. Under those conditions, heat tracing and/or insulation of capillaries is recommended or a temperature compensator can be applied.

- Typically used for applications with high vacuum in combination with high temperatures
- This fluid is not approved for food or pharmaceutical applications

SPECIFICATIONS

OPERATING TEMPERATURE	DESIGN TEMPERATURE	FREEZING POINT TEMPERATURE
-10/+315 °C	+315°C	-10°C
TYPE	VISCOSITY	DENSITY
Silicone	38.0 cSt	1.07 kg/dm ³

Note: viscosity and density at 25°C

VAPOUR PRESSURE RESULTS

BSO-18

BSO-20 is a silicone fill fluid designed as a fluid for applications where high vacuum in combination with elevated temperatures are present. The freezing point of this fill fluid is at +20°C, thus not recommended for cold outdoor applications. Under these conditions, heat tracing and/or insulation of capillaries is recommended, or a temperature compensator can be applied. Its high viscosity may result in long response times. Due to its high viscosity it is not recommended using 1mm ID capillary.

- Typically for applications where high vacuum in combination with high temperatures
- This fluid is not approved for food or pharmaceutical applications

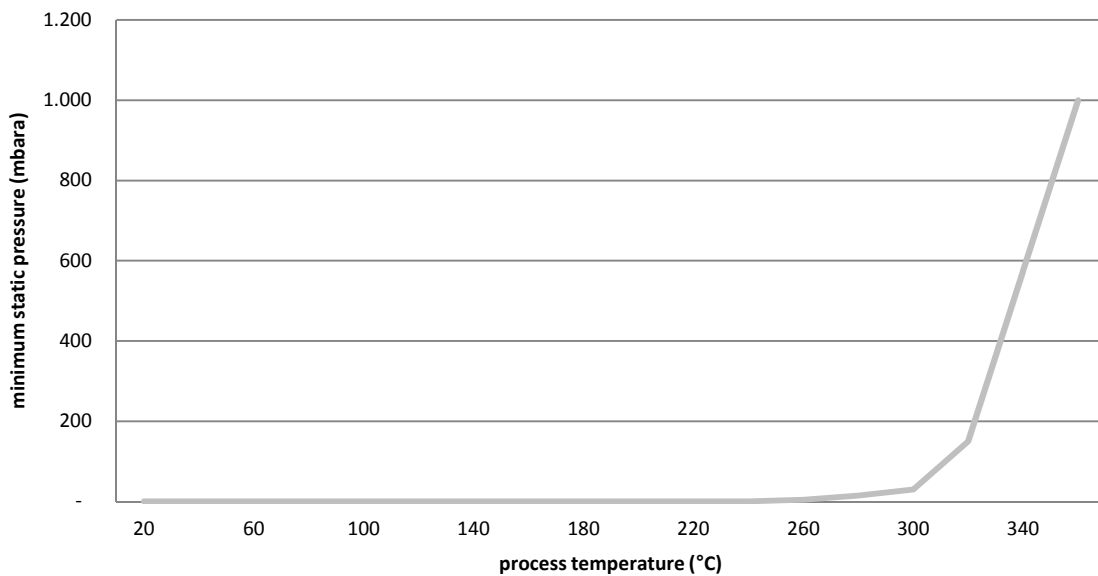

SPECIFICATIONS

OPERATING TEMPERATURE	DESIGN TEMPERATURE	FREEZING POINT TEMPERATURE
+20/+350 °C	+400°C	+20°C
TYPE	VISCOSITY	DENSITY
Silicone	175.0 cSt	1.09 kg/dm ³

Note: viscosity and density at 25°C

VAPOUR PRESSURE RESULTS

BSO-20

BSO-21 is a silicone fill fluid designed for applications where high vacuum in combination with elevated temperatures are present. Major difference with the BSO-20 is that it is better suitable for lower process temperatures. Due to its high viscosity it is not recommended using 1mm ID capillary.

- Typically for applications where high vacuum in combination with elevated temperatures are present
- This fluid is not approved for food or pharmaceutical applications

SPECIFICATIONS

OPERATING TEMPERATURE	DESIGN TEMPERATURE	FREEZING POINT TEMPERATURE
-40/+315 °C	+315°C	-50°C
TYPE	VISCOSITY	DENSITY
Silicone	125.0 cSt	1.07 kg/dm ³

Note: viscosity and density at 25°C

VAPOUR PRESSURE RESULTS

BSO-21

BSO-22 is the standard silicone fill fluid. It has a good balance of all the different specifications and is therefore used in more than half of the diaphragm seal applications. It has a maximum temperature of 200 °C and its freezing point exceeds the temperature range for proper functioning of the diaphragm seal system.

- The standard silicone fill fluid
- This fluid is not approved for food or pharmaceutical applications

SPECIFICATIONS

OPERATING TEMPERATURE	DESIGN TEMPERATURE	FREEZING POINT TEMPERATURE
-50/+200 °C	+204°C	-84°C
TYPE	VISCOSITY	DENSITY
Silicone	20.0 cSt	0.95 kg/dm ³

Note: viscosity and density at 25°C

VAPOUR PRESSURE RESULTS

BSO-22

BSO-25 is an inert CTFE filling fluid that is typically used for chlorine and oxygen applications. The design temperature exceeds the temperature limits for proper functioning of the diaphragm seal system.

- Typically used for chlorine and oxygen applications
- Used in silicon free environments
- This fluid is not approved for food or pharmaceutical applications

SPECIFICATIONS

OPERATING TEMPERATURE	DESIGN TEMPERATURE	FREEZING POINT TEMPERATURE
-40/+250 °C	+300°C	-40°C
TYPE	VISCOSITY	DENSITY
Inert	31.5 cSt	1.87 kg/dm ³

Note: viscosity and density at 25°C

VAPOUR PRESSURE RESULTS

BSO-25

BSO-36 is a silicone fill fluid and because of its low viscosity can be considered as a substitute of BSO-22 in the rare cases where the latter cannot meet the response time requirements. The maximum temperature is of 150°C.

- Typically used for cold process temperatures
- This fluid is not approved for food or pharmaceutical applications

SPECIFICATIONS

OPERATING TEMPERATURE	DESIGN TEMPERATURE	FREEZING POINT TEMPERATURE
-70/+150 °C	+150°C	-70°C
TYPE	VISCOSITY	DENSITY
Silicone	10.0 cSt	0.93 kg/dm ³

Note: viscosity and density at 25°C

VAPOUR PRESSURE RESULTS

BSO-36

BSO-40 is the standard fill fluid for food and pharmaceutical applications. It has FDA approvals 21CFR 172.856 as direct and 21CFR 174.5 as indirect food additive. Its CAS registration number is 68583-51-7. It is a derivate of coconut oil and propylene glycol.

- This fluid is approved for food or pharmaceutical applications
- FDA approvals 21CFR 172.856 and 21CFR 174.5
- CAS registration number is 68583-51-7

SPECIFICATIONS

OPERATING TEMPERATURE	DESIGN TEMPERATURE	FREEZING POINT TEMPERATURE
-15/+225 °C	+225°C	-19°C
TYPE	VISCOSITY	DENSITY
Polyol diester	9.5 cSt	0.92 kg/dm ³

Note: viscosity and density at 25°C

VAPOUR PRESSURE RESULTS

BSO-40

BSO-41 is a silicone fill fluid and because of its very low viscosity should be considered as a replacement of BSO-22 in the rare cases where the latter cannot meet the response time requirements. It is considered as an excellent second fill for temperature compensator applications.

- Used as secondary fill for Temperature Compensator
- This fluid is not approved for food or pharmaceutical applications

SPECIFICATIONS

OPERATING TEMPERATURE -80/+120 °C	DESIGN TEMPERATURE +120°C	FREEZING POINT TEMPERATURE -80°C
TYPE Silicone	VISCOSITY 5.0 cSt	DENSITY 0.92 kg/dm ³

Note: viscosity and density at 25°C

VAPOUR PRESSURE RESULTS

BSO-41

BSO-42 is a Badotherm developed blend of silicone fill fluids. It has the same maximum temperature as BSO-20 but far lower freezing point and lower viscosity resulting in better response time performance than BSO-20. As such it is the standard fill fluid for high temperature applications.

- Typically for high temperature applications
- This fluid is not approved for food or pharmaceutical applications

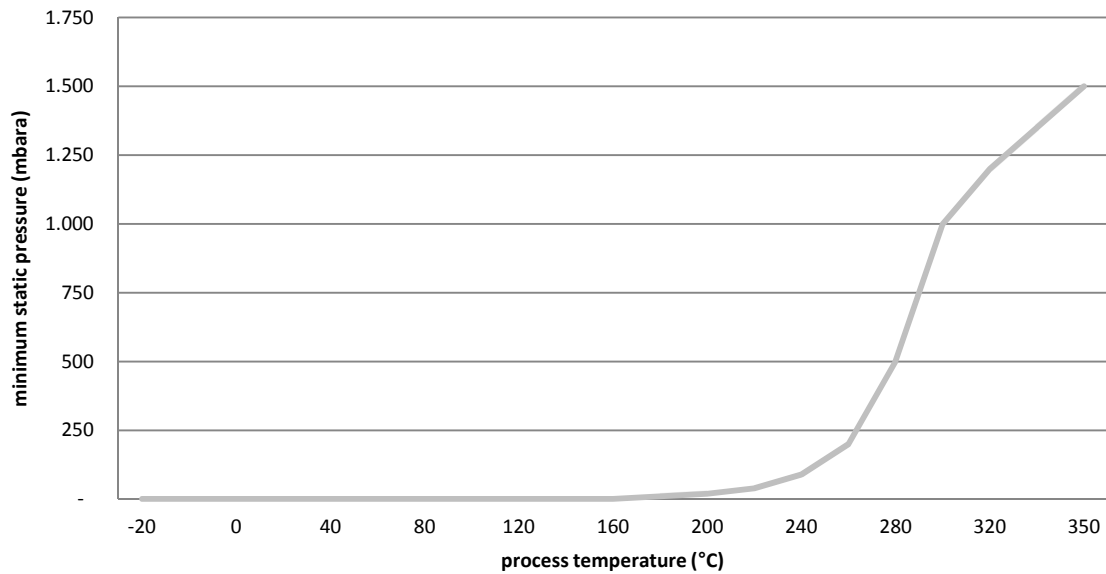

SPECIFICATIONS

OPERATING TEMPERATURE -20/+350 °C	DESIGN TEMPERATURE +400°C	FREEZING POINT TEMPERATURE -20°C
TYPE Silicone	VISCOSITY 57.6 cSt	DENSITY 1.07 kg/dm ³

Note: viscosity and density at 25°C

VAPOUR PRESSURE RESULTS

BSO-42

BSO-45 is a lubricant preparation and is especially developed for processes that require both cooling and heating. It is also recommended for use in food processing plants. This fluid meets the requirement established by the FDA at 21 CFR 178.3620(b).

- This fluid is approved for food or pharmaceutical applications
- FDA approvals 21CFR 178.3620(b)

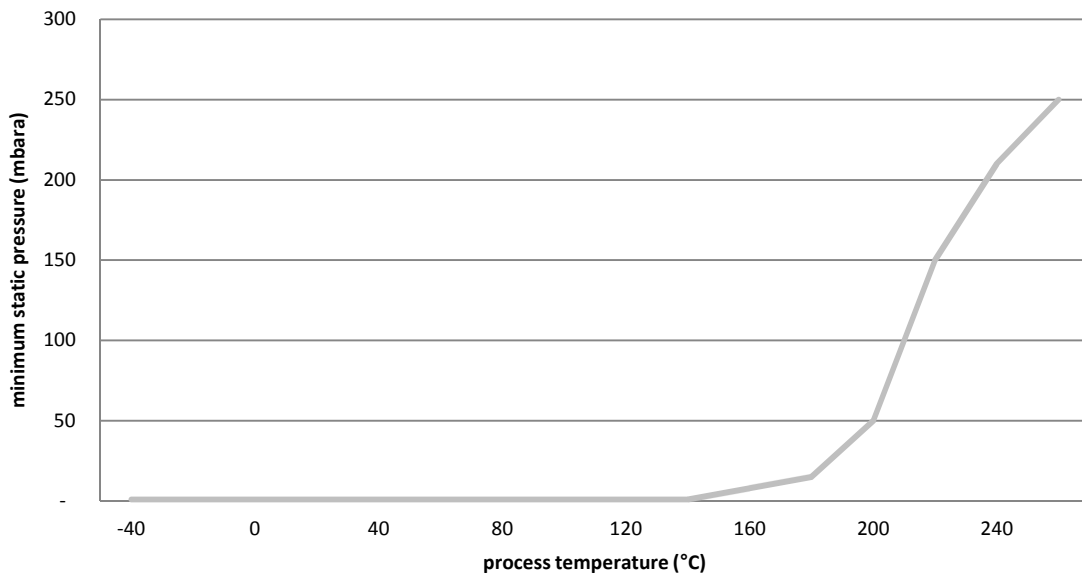

SPECIFICATIONS

OPERATING TEMPERATURE	DESIGN TEMPERATURE	FREEZING POINT TEMPERATURE
-40/+250 °C	+250°C	-48°C
TYPE	VISCOSITY	DENSITY
Hydrogenerated mineral oil	9.8 cSt	0.83 kg/dm ³

Note: viscosity and density at 25°C

VAPOUR PRESSURE RESULTS

BSO-45

BSO-46 is a high performance, highly stable synthetic heat transfer fluid. Its freezing point exceeds the temperature range limits for proper functioning. A specific feature of this fill fluid is that it is self-restoring, meaning that even when its design temperature is exceeded, the fill fluid specifications remain intact after cooling down.

- This fluid is not approved for food or pharmaceutical applications

SPECIFICATIONS

OPERATING TEMPERATURE -5/+345°C	DESIGN TEMPERATURE +345°C	FREEZING POINT TEMPERATURE -32°C
TYPE Hydrogenated terphenyl	VISCOSITY 29.6 cSt	DENSITY 1.01 kg/dm ³

Note: viscosity and density at 25°C

VAPOUR PRESSURE RESULTS

BSO-46

BSO-48 is a Badotherm designed blend of silicone fill fluids. It has better temperature specification than the BSO-42 (another Badotherm blend) especially a better performance at low pressure (high vacuum) combined with high operating temperatures. As such it is an appropriate fill fluid for the boundaries of high temperature applications.

- Typically for high temperature applications
- This fluid is not approved for food or pharmaceutical applications

SPECIFICATIONS

OPERATING TEMPERATURE -20/+410°C	DESIGN TEMPERATURE +420°C	FREEZING POINT TEMPERATURE -32°C
TYPE Silicone	VISCOSITY 57.6 cSt	DENSITY 1.08 kg/dm ³

Note: viscosity and density at 25°C

VAPOUR PRESSURE RESULTS

BSO-48

Flushing flange is used for flushing solution combined with diaphragm seals. This type of flushing ring is clamped between process nozzle and diaphragm seal and aligned by the exact same bolt holes as the process nozzle and the diaphragm seal. The flushing flange can be combined with the BF and BRf seal and BC and BRC seal.

Reducer flange is used to mount a larger diaphragm seal to a smaller process connection. This type of reducer flange is clamped between process nozzle and diaphragm seal. Eccentric reducer flanges can be supplied to prevent process media remaining in the reducer ring when mounted in vertical position. The reducer flange can be combined with the BF and BRF seal as well as the BC and BRC type.

INTRODUCTION

It is a recognised phenomenon in the process industry that higher process pressure and temperature can improve the overall efficiency. Currently, when measuring with a transmitter with Diaphragm Seals the temperature limit of Diaphragm Seal applications is set at 420°C as this is the maximum allowed temperature of the filling fluid.

HIGH TEMPERATURE DIAPHRAGM SEAL

Badotherm has developed Diaphragm Seal that can withstand process temperatures up to 600°C. To enable a proper functioning of the Diaphragm Seal at these extreme process temperatures a revolutionary new design and principle is used. The novelty of the design is as such that Badotherm has a Patent on the High Temperature Diaphragm Seal (HTDS).

The HTDS is extensively tested in different circumstances and with various process temperatures. The graph

presents the temperature reduction measured in the diaphragm chamber compared to a normal Diaphragm Seal. The HTDS is suitable for both gauge and differential pressure transmitters.

TEMPERATURE AND STATIC PRESSURE LIMITS

The maximum temperature limit is determined by a combination of the fill fluid, and the material of the body and of bolts. With AISI-321H body material and 1.4980 bolt material the maximum temperature is 600°C (material specifications and maximum temperature according the ASME B16.5 standard). The maximum operating pressure depends on the flange rating combined with process temperature. The table below presents the temperature and pressure limits for 3 selected filling fluids.

	BSO-46	BSO-42	BSO-02
Temperature Limits			
Max. Process temp.	600°C	550°C	600°C
Min. Ambient temp.	0°C	-10°C	-40°C
Max. Ambient temp.	50°C	50°C	50°C
dP Static Pressure

INTRODUCTION

In today’s process industry there are many processes that operate with very low pressures, < 100 mbar. An example of such a process is Nitrogen blanketing which is a commonly used technique to prevent process gases entering the atmosphere. To obtain this, a small nitrogen overpressure of approximately 10 mbar is applied on a vessel with these gases. Accurate measurement of this small overpressure is necessary to minimise or even avoid interference with the process in the vessel. Besides that a significant cost reduction is achieved by limiting the consumption of nitrogen to an absolute minimum.

LOW PRESSURE MEASUREMENT WITH DIAPHRAGM SEALS

Difficulties arise when this technique is applied in a corrosive environment. In these circumstances it is often mandatory to use pressure measurement devices equipped with Diaphragm Seals. However, the use of a standard Diaphragm Seal in combination with the very low overpressure ranges implies relative high temperature effects. These high temperature effects, and especially ambient temperature effects, result in unstable, unreliable and inaccurate pressure measurement. And this subsequently results in poor control of the process.

SOLUTION DEVELOPED

After thorough analysis of the process data and requirements, Badotherm developed a Diaphragm Seal for low pressure GP applications. This solution is referred to as LGP and can be used in combination with several seal types. Test results obtained by measuring low gauge pressures showed that the minimum GP range reduces from 80 mbar with a standard Diaphragm Seal to only 5

mbar with the LGP Diaphragm Seal. Similarly the ambient temperature effect reduces from 0.4 mbar per 10°C to 0.03 mbar, while the process temperature effect reduces from 0.39 to 0.09 mbar.

Besides the accurate measuring of low pressure and limiting the consumption of nitrogen two other issues were solved. Firstly, the way of mounting the transmitter to the vessels has no effect on the zero and span adjustments of the transmitter. Secondly, there is no effect on the performance by a change in density of the fill fluid caused by ambient temperature fluctuations.

TECHNICAL SPECIFICATIONS

The Diaphragm Seal type LGP is standard manufactured in AISI316(L). It can also be supplied with all kinds of exotic materials as wetted parts. The LGP solution needs to be mounted on a DP transmitter.

	STD 3"	LGP 3"
Min. GP range (mbar)	80	5
Min. Capillary length (mtr)	direct	0.5
Ambient temp. effect (mbar)		
Capillary (per mtr)	0.4 /10°C	0.03 /10°C
Transmitter	0.19 /10°C	0.02 /10°C
Process temp. effect (mbar)		
Diaphragm Seal	0.39 /10°C	0.09 /10°C

CALCULATION EXAMPLE

Below a calculation example with the above mentioned specifications is presented.

Temp. at calibration	20°C	20°C
Ambient temp.	40°C	40°C
Process temp.	140°C	140°C
Temp. effect (mbar)		
Diaphragm Seal	4.68	1.08
Capillary	4	0.3
Transmitter	0.38	0.04
Total temp. effect (mbar)	9.06	1.42
Total Probable Error (TPE)	11.3%	1.8%

INTRODUCTION HYDROGEN PERMEATION

Hydrogen is the lightest and most abundant chemical element. Hydrogen is not considered to be corrosive, still problems with Diaphragm Seals can occur under specific circumstances. These can be with high process temperature in combination with high process pressure, a galvanic reaction, or with high temperature steam.

Hydrogen is normally found in a diatomic state, H² molecules, composed of two hydrogen atoms. In a diatomic state, molecules will not permeate the diaphragm. However, if the hydrogen splits into two H⁺ atoms, it can permeate the diaphragm as H⁺ ions are smaller than the space between molecules of the diaphragm material.

After permeation through the diaphragm, H⁺ ions can unite into H² molecules which become trapped inside the Diaphragm Seal. H² will dissolve into the Diaphragm Seal fill fluid and over time the seal fill fluid will become saturated, a hydrogen bubble will appear, and the measurement will fail.

When the process pressure drops, the trapped H² ions are not able to permeate back and remain in the Diaphragm Seal system. With the H² molecules in the system the pressure within the Diaphragm Seal could remain as high as the original process pressure. The result is that the diaphragm will bulge, which leads to a zero and span shift and reduces the performance of the Diaphragm Seal system.

SOLUTION DEVELOPED

To protect the diaphragm seal diaphragm against the H⁺ ions permeation a Gold Coating is advised. Badotherm offers a 40µm and 25µm thickness for Gold Coating on Diaphragm Seals.

Normally, the temperature limit of Gold Coating is 280°C, because of by the intermediate layer of nickel. Above this limit a normal Gold Coating will be damaged or even detached from the diaphragm. Together with TNO Delft, which is an independent Dutch Research Organisation, Badotherm developed a new procedure to plate the gold directly to the diaphragm without any intermediate layer. With this new type of procedure the temperature limit on Gold Coating is increased to 400°C.

The 40µm Gold Coating thickness was engineered and designed specifically for the Hycon project in The Netherlands. Because in this project the operating temperatures (320°C) and pressures (180 bar) were extreme, additional tests on various thicknesses were executed by TNO. The result was that only a 40µm thickness could warrant the non porosity for H⁺ ions.

CHEMICAL RESISTANCE

As the Gold Coating protects the diaphragm to even the smallest molecules it is also very suitable to increase the Chemical Resistance of the Diaphragm Seal. For protection against Hydrogen Permeation the diaphragm only is coated, but to ensure Chemical Resistance the Gold Coating is extended to the outside diameter of the gasket surface.

Hydrogen Permeation

Hydrogen Permeation and Chemical Resistance

TECHNICAL SPECIFICATIONS

INTRODUCTION

It is extremely complex to measure low pressures of at high process temperatures with Diaphragm Seals. The available fluids that can withstand these temperature and pressure conditions mostly have a very high viscosity. Additionally, when there is also a considerable capillary length (> 1 meter) required the viscosity of these fill fluids, certainly at lower ambient temperatures, becomes so high that the response time of the transmitter with Diaphragm Seal becomes unacceptable.

SOLUTION DEVELOPED

To overcome this problem Badotherm has designed a 'Temperature Compensator' solution. This description does not completely cover the functionality of the design because it not only compensates for temperature, but also for response time.

The compensator has a specially designed second diaphragm that is placed between the Diaphragm Seal and the transmitter. The first part between the Diaphragm Seal and the Temperature compensator is filled with high temperature fill fluid with a high viscosity. After the Temperature Compensator the process temperature is reduced to approximately ambient temperature and those conditions are acceptable for fill fluids with a low viscosity. The lower viscosity, even at lower ambient temperatures and longer capillary lengths, reduces the overall response time of the Diaphragm Seals System.

Example of Temperature Compensator with BSO-21 and BSO-36

The temperature compensator is available for all Diaphragm Seals to be combined with pressure transmitters.

INTRODUCTION

A leaking diaphragm is often detected too late, with harmful and costly consequences to the process or the environment. As a solution for this problem Badotherm has invented the Diaphragm Leakage Detection system for Diaphragm Seal Applications. The advantages of the DLD system are:

- Early alert: diaphragm leaks are discovered immediately after a leak occurs
- Cost-saving: instant action can be taken to avoid costly production contamination
- Environmental protection: harmful release of aggressive process fluids can be prevented
- Process protection: formation of bacteria is prevented

PRINCIPLES DLD SYSTEM

When a diaphragm is damaged, the process medium will seep into the seal filling fluid, changing the conductivity of the fluid. This change in conductivity is detected by a built-in sensor, with an output to an alarm or any kind of output signal.

The DLD system is mainly designed for the food and beverage industry. There, a leak in the diaphragm can lead to unwanted formation of bacteria, caused by the residues in the Diaphragm Seal system. The DLD system is of course also suitable in the chemical and petrochemical industry to avoid wastage and environmental dam-

age by a leaking diaphragm. The DLD system can restrict the damage by an early detection of the leakage.

RANGE OF APPLICATION

The DLD system can be put on several Badotherm Diaphragm Seal system with a flanged or sanitary process connection larger than 1.5". The DLD is suitable for aggressive process media. Here, it is possible that less protected parts of the Diaphragm Seal system would be corroded, by the invasion of process fluid. This could lead to a dangerous and harmful release of process fluid.

TECHNICAL SPECIFICATIONS

The DLD can be executed with EX proof head without electronics and with a sensitivity sensor <math>< 1\text{m}\Omega</math>.

INTRODUCTION

Diaphragm seals with a capillary connection can be installed at vulnerable locations, with high concentration of chloride, high temperatures, or locations that can be influenced by mechanical damage or a combination of all three. One of the weakest points in a Diaphragm Seal System is the connection between the seal and the capillary and all of the influences mentioned above can easily damage the welded capillary connection. When the capillary connection is damaged the Diaphragm Seal System can even start leaking which results in a loss of measurement.

SOLUTION DEVELOPED

To overcome this problem Badotherm has designed a 'Heavy Duty Support Tube' solution. This description does not completely cover the functionality of the design, because it not only can be used for heavy duty environments, but also at locations where the weld of the capillary should be protected against environmental chloride stress corrosion.

Key features of the Heavy Duty Support tube are:

- Reduction of temperature on capillary in order to prevent burning of personnel
- Reduce the chance of mechanical damage on capillary connection
- Prevent chloride stress corrosion on the capillary weld (IP68 execution only)

The Heavy Duty Support Tube is available in two types, the IP57 tube and the IP68. The IP57 has the function of temperature reduction and reduction of mechanical damage. The IP68 edition has the extra feature that it hermetically seals the capillary weld from environmental influences such as chloride fumes and fluid. The soldered tube end prevents the fumes and the rain combined with these fumes to 'attack' welded connection.

TECHNICAL SPECIFICATIONS

The Heavy Duty Support Tube has had extensive testing in the process simulation environment in the Badotherm facility and in the "Field" with key customers. The temperature test has proven that the temperature reduction is significantly. When a process temperature of 300°C in an environment temperature of 20°C is applied, the Diaphragm Seal temperature on the end of 80mm extension tube reduces to approximately 70°C. The 150mm extension tube reduces the temperature at the capillary side to approximately 35°C. Both temperatures are safe for personnel and nearby equipment.

INTRODUCTION

The raised face covered Diaphragm Seal is the solution for flanged seals with exotic wetted parts. The Diaphragm Seals are designed to prevent contact of the process medium with the AISI316 seal body materials. All wetted parts of BRF/BRC type Diaphragm Seals are covered with an exotic diaphragm material.

SOLUTION DEVELOPED

The double weld technology makes it possible to keep the wetted parts (a) of the diaphragm material properties uninfluenced by the welding operation to the 316 body material (b). The inner weld (c) is located on the wetted part and is welded with the latest resistance weld technology. The resistance weld is helium tested in order to exclude leaks in the welded area. The outer weld (d) is welded with TIG welding technology and is a non-wetted part. The gasket surface (e) between the resistance weld and the TIG weld is fully covered with the exotic diaphragm material and has the appropriate roughness.

TECHNICAL SPECIFICATIONS

The table below presents the various Exotic diaphragm materials that can be used in combination with 316 body material.

	BRF	BRC

About Badotherm

We are a European manufacturer of mechanical process instruments with a worldwide distribution network. We have regional Diaphragm Seal assembly facilities in Europe, the Middle East, India, the Far East and the Americas. We design, engineer and manufacture Diaphragm Seals, Pressure Gauges, Temperature Gauges and Thermowells, Instrument Valves and Manifolds. Next to our product offering, we develop tailor-made solutions for challenging conditions in the field of Diaphragm Seal measurements. Headquartered in the Netherlands, we employ over 225 people in seven different countries.
